ABSTRACT (Continue on reverse if necessary and identify by block number) Abstract: The A/F32T-9 Large Turbo Fan Engine, Enclosed Noise Suppressor System (T-9 NSS) at Sky Harbor International Airport, Phoenix AZ was surveyed to determine noise levels at 100 meters. With an F101 engine operating at afterburner power the highest measured Overall Sound Level, A-Weighted (OASLA) was 88.7 dB(A). The measured OASLA values exceeded the 77 dB(A) criterion at all but five of the twenty-four sampling positions. Handwritten: Test conducted at 100 meters from the engine.

ACKNOWLEDGMENTS

The dedicated efforts of the following survey team members in collecting data during the early morning hours are sincerely appreciated: Maj John C. Ellis, II, 1Lt Laura G. Jehrde, 2Lt Anthony T. Zimmer, 2Lt Winston J. Shaffer, II, MSGT Abel B. de la Rosa, and SSgt Michael K. Lazenby. The entire survey ran smoothly thanks to the invaluable work of Mr Art Woytek of SA ALC/MMIMH, Kelly AFB TX, in coordinating the efforts of many different people prior to the survey. We also wish to thank A1C Brian Fallon of the 25 WS-Det 15, Luke AFB, for providing critical on site meteorological data in support of our noise survey. Finally, we want to thank the engine maintenance personnel of the 161 AFEFG, Phoenix ANG Stn for surveying and marking the sampling locations, and for providing ready access to needed working space.

I. INTRODUCTION

A. Purpose: This report provides the results of the analysis of the noise data recorded during the 12 November 1986 survey of the A/F32T-9 Large Turbo Fan Engine, Enclosed Noise Suppressor System (T-9 NSS) at the 161 AREFG, Sky Harbor International Airport (IAP) AZ. The T-9 NSS item managers, SA-ALC/MMIMH, Kelly AFB TX, requested the noise survey to support their First Article Test (FAT) on the Sky Harbor IAP facility.

B. Problem: Data from the analysis of noise tapes collected during a survey of the first T-9 NSS at McConnell AFB KS, indicated the system was exceeding the contractually specified maximum noise level of 77 decibels, A-weighted (dB(A)) measured at any location 100 meters from the building. (Reference 4 contains a description of the T-9 NSS facility.) However, conditions at the McConnell AFB T-9 NSS site were less than ideal for the collection of noise data recordings. The temperature, humidity, and wind speed were often outside the range of acceptable values for the collection of accurate noise data recordings. Other buildings near the T-9 NSS at McConnell AFB, shielded some measurement locations from direct noise exposure and exposed some measurement locations to reflected noise. Background noise levels during the survey at the McConnell AFB T-9 NSS were high because the site is near an active runway. Given the operational constraints at McConnell AFB, it was impossible to collect noise data recordings that were not affected by takeoff, landing, and flyover noise from aircraft.

Measurements were taken at Sky Harbor IAP to reassess the noise reduction effectiveness of the T-9 NSS under more favorable conditions. The temperature, humidity, and wind speed were within the range of acceptable values during the survey of the facility at the Phoenix IAP. Also the T-9 NSS at the Sky Harbor IAP site is located farther away from surrounding buildings and other sound reflecting sources than the T-9 NSS at the McConnell AFB site. Finally, to minimize the background noise, the survey at the Phoenix IAP was conducted from 0100 to 0400 hours.

The operational shake-down test requirements of the T-9 NSS were satisfied for the eight engines tested at McConnell AFB. It was not practical to transport the eight engines and the required operating personnel to the Sky Harbor IAP and rerun all eight engines to allow the collection of noise data under improved conditions. SA-ALC/MMIMH selected the F101 engine for the limited survey of the T-9 NSS at Sky Harbor IAP because it had produced the highest measured Overall Sound Level, A-weighted (OASLA) values of the eight engines measured during the McConnell AFB KS survey.

C. Scope: Far field noise data are reported and compared with the 77 dB(A) criterion. The results of the Sky Harbor IAP survey are summarized by presenting the measured Overall Sound Pressure Level (OASPL) and the OASLA for background noise (with no engine operating) and with an F101 engine operating at intermediate power and afterburner power at each of the twenty-four 100 meter (m) locations surveyed.

II. DISCUSSION

A. Survey Methods: Far field noise data from the T-9 NSS were collected at a distance of 100 m from the test cell at ten degree increments. The data were collected during the early morning hours (0100 - 0400 hours) when air traffic noise from the airport would be minimal. Figure 1 in Appendix A shows the T-9 NSS orientation relative to 38 possible microphone measurement sites on two 100 m (328 feet) semicircles. The center of the front semicircle was located on the ground directly beneath the intersection of the engine centerline and a plane passing through the exhaust nozzle. The center of the back semicircle was located at the center of the exhaust stack. This two center approach was used because the T-9 NSS is designed with two main exit ports for the noise generated: the air inlets and the exhaust stack. These two exit ports for noise are separated by a relatively large distance (over 100 feet) causing the T-9 NSS to act like a two point noise source. Noise measurements would have to be taken at a much greater distance than the 100 m radius to allow the T-9 NSS to be considered a single point source. Source noise levels measured at a farther distance would have been lower and possibly too close to the background noise levels to allow clear determination of the source characteristics.

Due to the presence of extremely rough terrain outside the installation boundary, noise data could only be collected at 24 of the 38 defined positions. The sampling positions from which data could not be completed included all defined positions from 330 degrees to 210 degrees. The noise levels for the 14 unsampled locations should be approximately equal to the symmetrical locations on the opposite side of the engine axis. Portable tape recording systems were used to obtain approximately 30 seconds of noise data on audio tape for later analysis at USAFOEHL. Three teams recorded data using separate systems at different points to allow data collection within the time allowed by the operating constraints of the engine. The microphone, attached to a hand-held pole, was pointed at the source (0 degree angle of incidence) and vertically scanned from 0.5 to 3 meters for a period of approximately 30 seconds during data acquisition at each measurement location. These samples were then time-integrated on a 1/3 octave band digital frequency analyzer to derive a root-mean-square sound pressure level. Vertical scanning and time-integrating together reduce anomalies frequently present in data acquired with a fixed height microphone.

B. Survey Results: The OASPL and OASLA values are presented as a function of the measurement location and power setting of the F101 engine (Table 1, Appendix A). The OASLA data for afterburner power are also plotted on a polar plot (Fig 2, Appendix A) showing the 77 dB(A) criterion as a reference line. The OASPL and OASLA values were calculated using the results of the 1/3 octave band analysis of recorded data for frequencies from 5 Hz to 10 kHz.

Meteorological data was recorded every fifteen minutes during collection of noise data from 0200-0400 hours. Conditions were extremely stable with a wind speed of 0-2 meters per second, a temperature of 55°F, a relative humidity of 55%, and a barometric pressure of 28.81 inches of mercury.

Background noise levels were measured at each of the 24 microphone locations to obtain an accurate representation of the ambient noise levels at each measurement site. To be certain a measured noise level is coming from the noise source being evaluated, the background noise level should be much lower than the measured total noise level (which includes both the background noise and the noise produced by the source). In practice, measured background levels should be ten or more decibels below the measured total noise levels. The correction for background noise is a function of the difference between the total noise level and the background noise level. The magnitude of the required adjustment for background noise decreases as the difference between the total noise level and the background noise level increases.³

Background corrections were not applied to the OASPL and OASLA values calculated for afterburner power and intermediate power operations of the F101 engine. At afterburner power where the measured total OASLA values exceeded the 77 dBA criterion, the corrections to the OASLA values would be 0.1 dBA or less for all the sampling locations.

Results of the 1/3 octave band analysis of recorded data for the frequency range 5 Hz - 10 kHz are presented both graphically and in table form (Appendix B) for each measurement location.

III. CONCLUSIONS

The Phoenix ANG Station T-9 Noise Suppressor System at the Sky Harbor IAP did not meet the 77 dB(A) criterion for all measurement locations with the F101 engine operating at afterburner power. Only the zero degree position and the first two angles on either side of zero were measured at 77 dB(A) or less. The highest recorded level of 88.7 dB(A) occurred at the 180 degree position (in line with the engine's exhaust). This value exceeds the criterion by 11.7 dB.
